Innovations in cartography: automated decryption, generalization, multiscale map

Speaker: **Alexander Kirichenko**

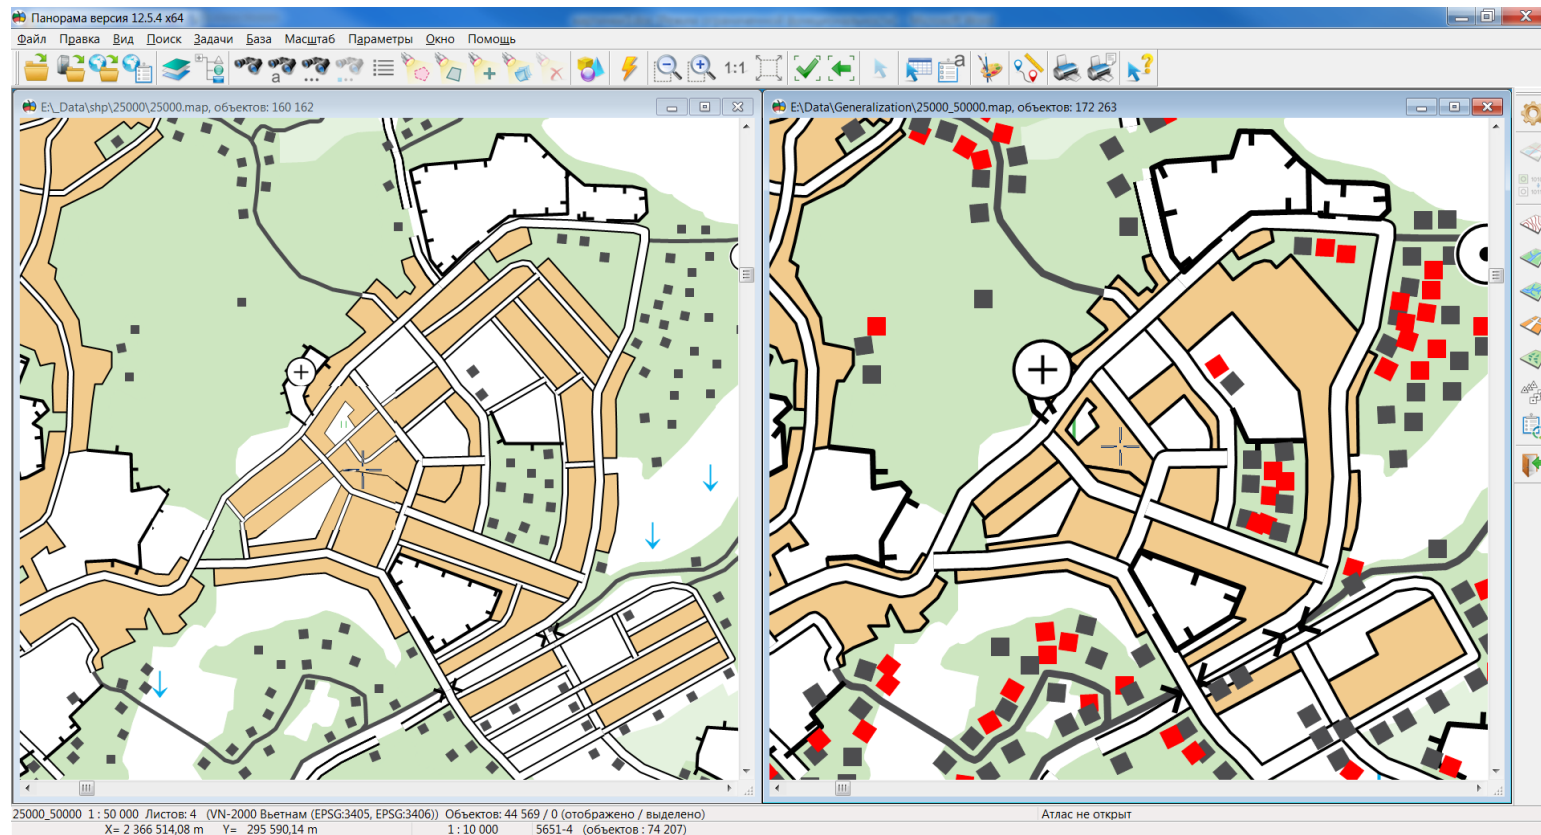

Automated Decryption and Vectorization

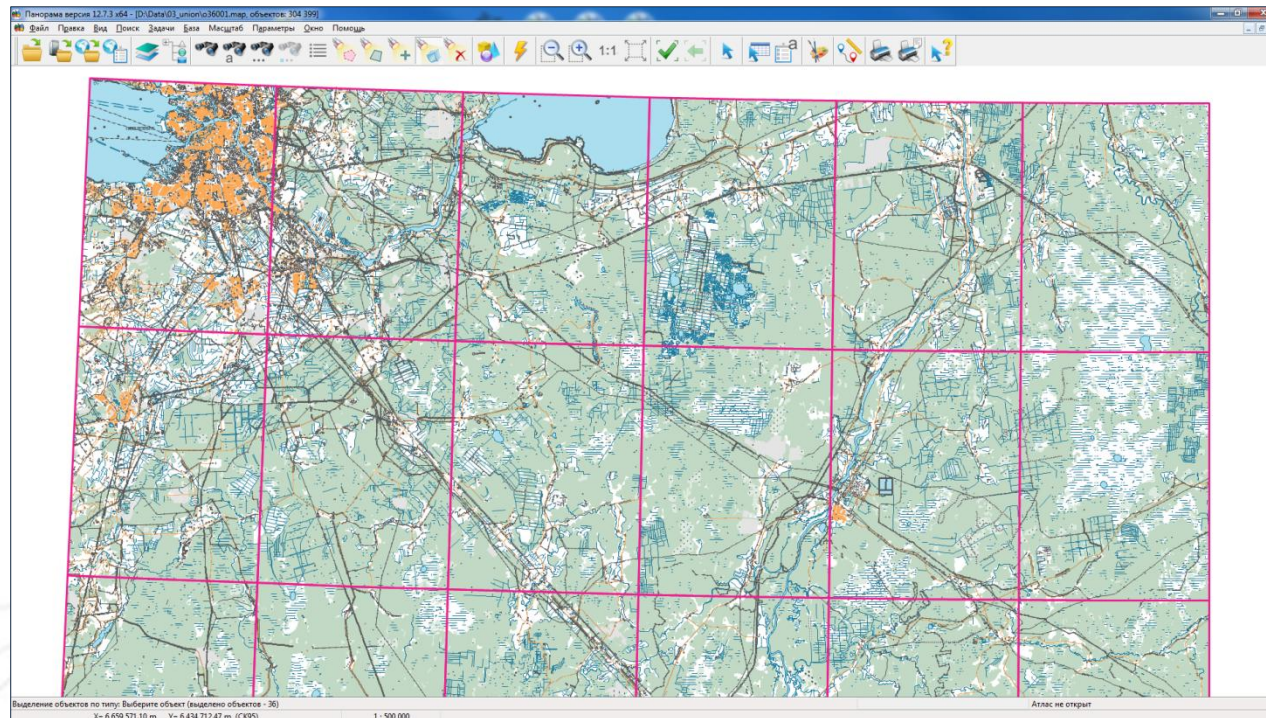

Multiscale maps

Automated generalization

Formation of nomenclature sheet

-  Initial map sheet frames
-  Derivative map sheet frame
-  Auxiliary lines (junction lines)
-  Lines of maximum divergence of points of objects coming to frame

Simplification of metrics and generalization of contours

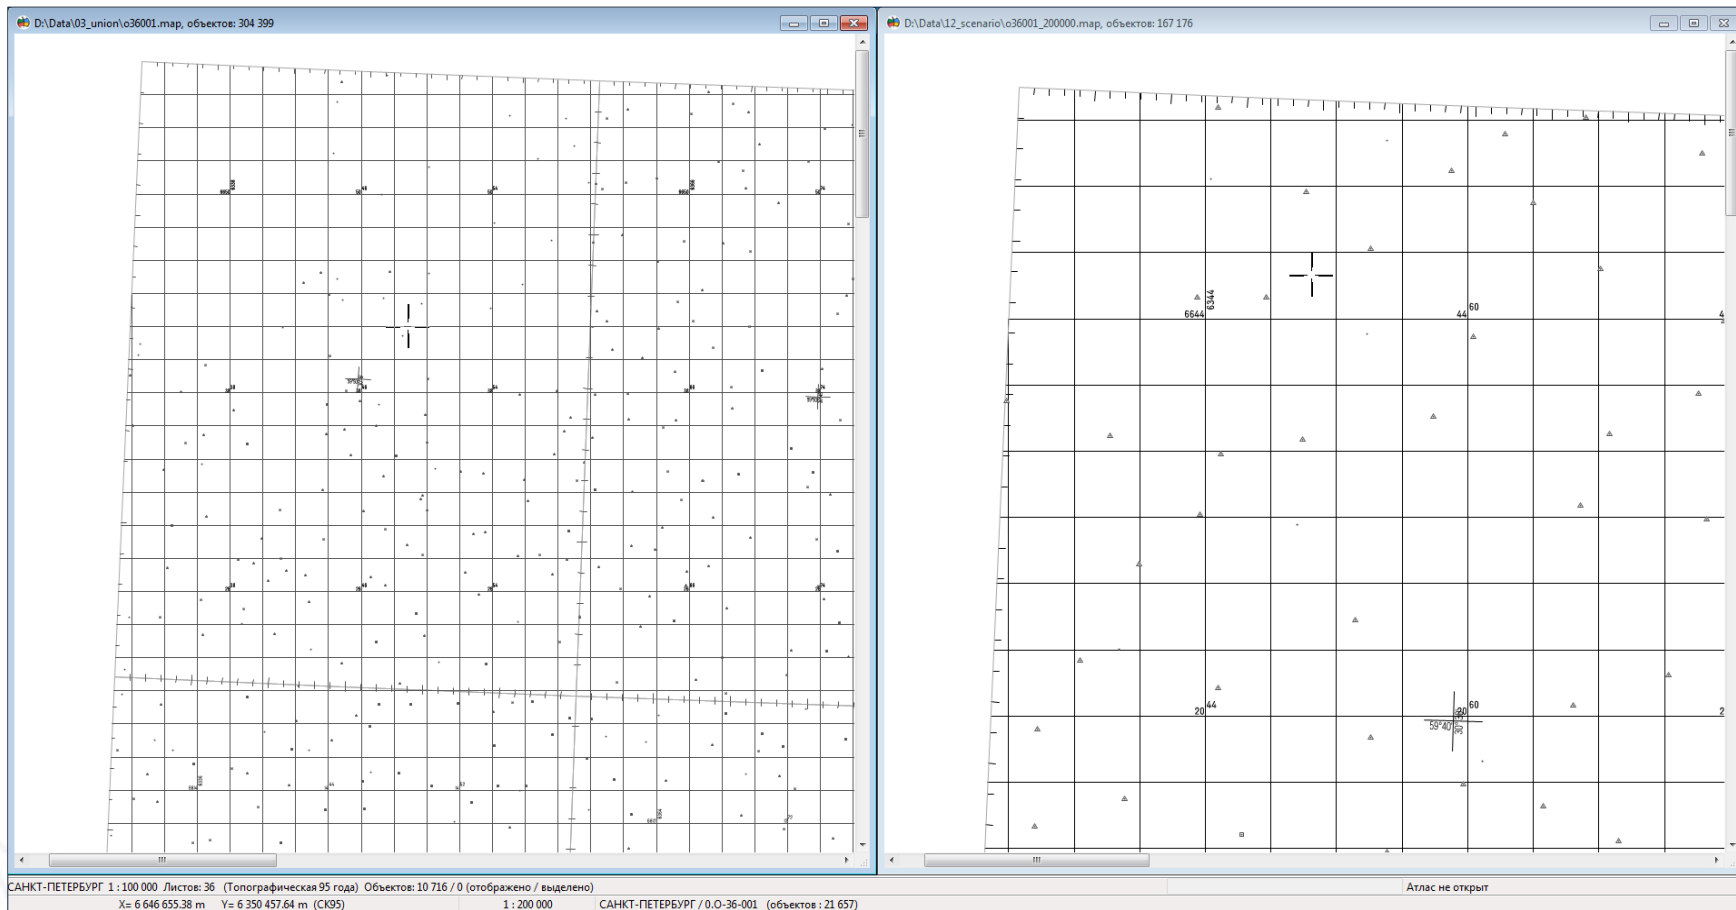

Filtering allows removing unnecessary points (located on one straight line or almost on one straight line)

Contour generalization is designed to smooth the metric description of linear and areal map objects.

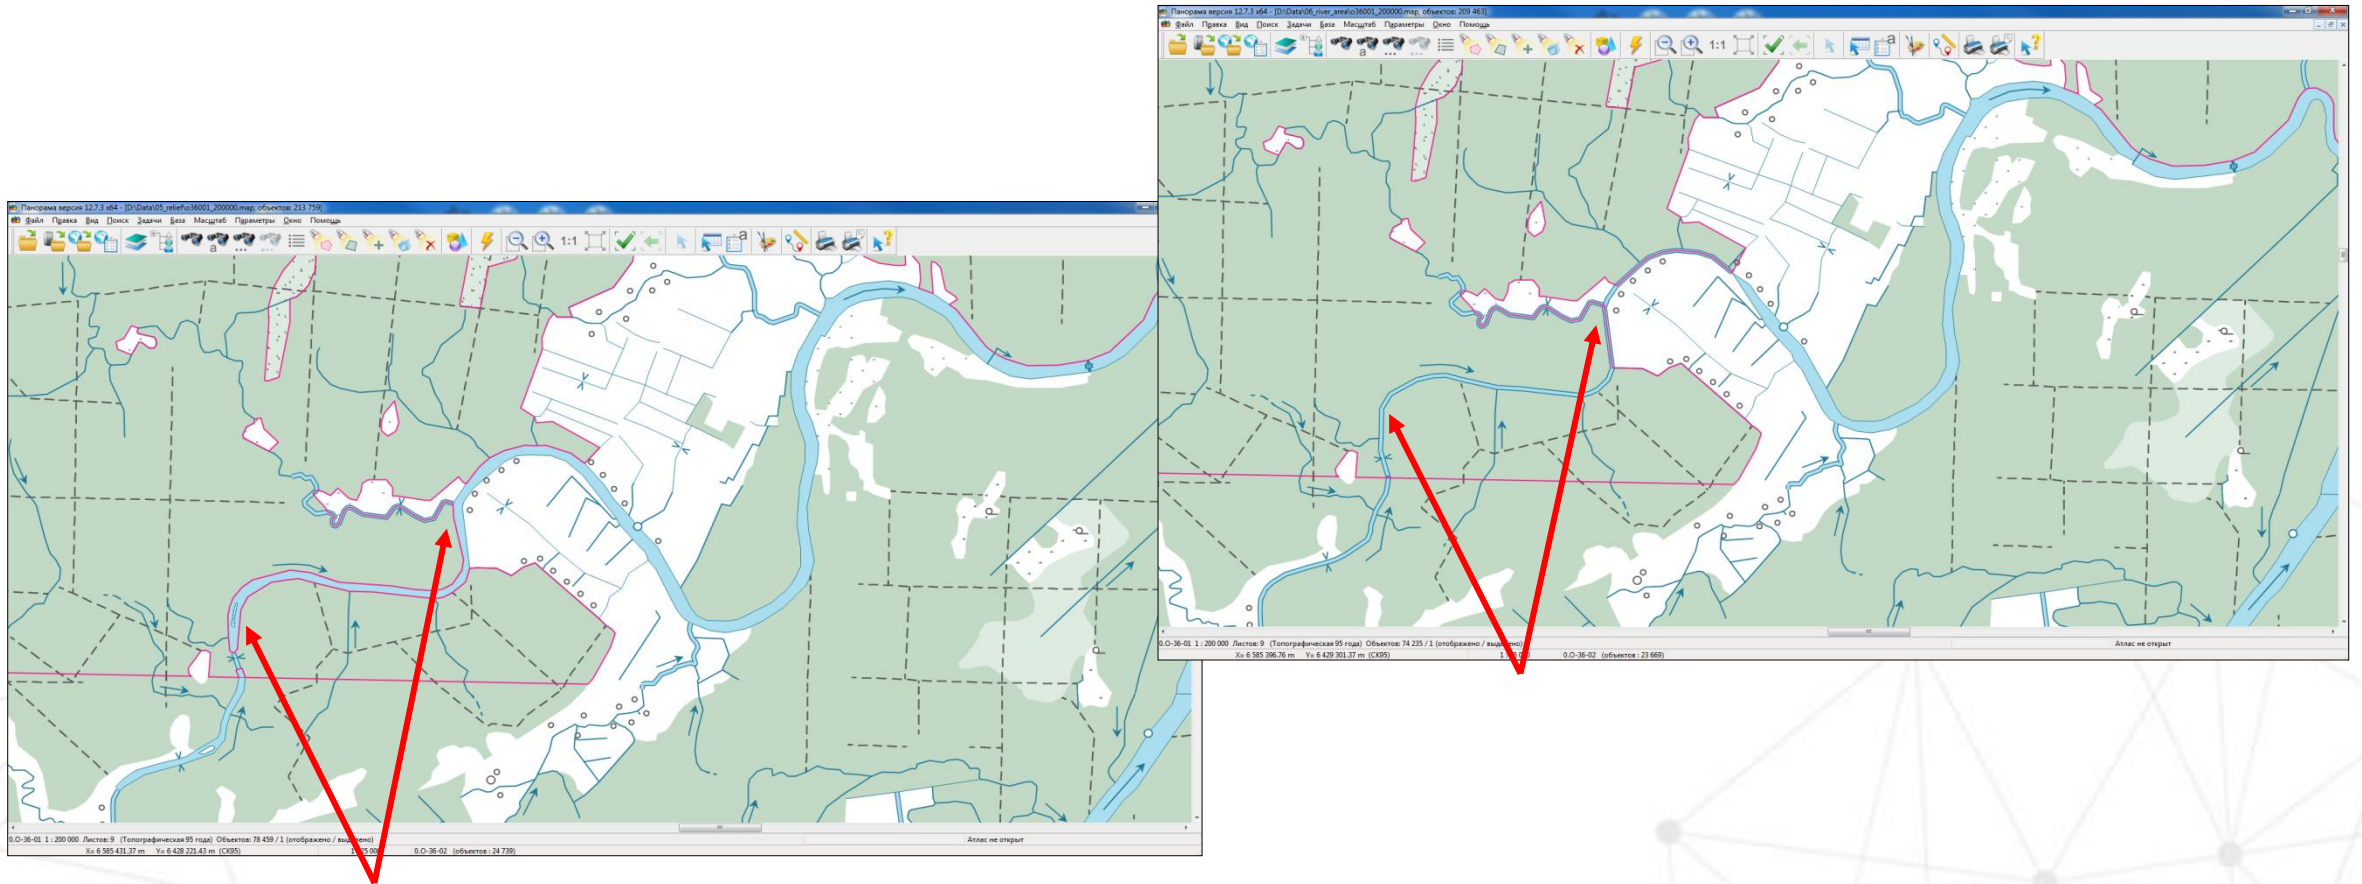

Generalization of mathematical, planimetric and elevation base objects

Automated terrain generalization

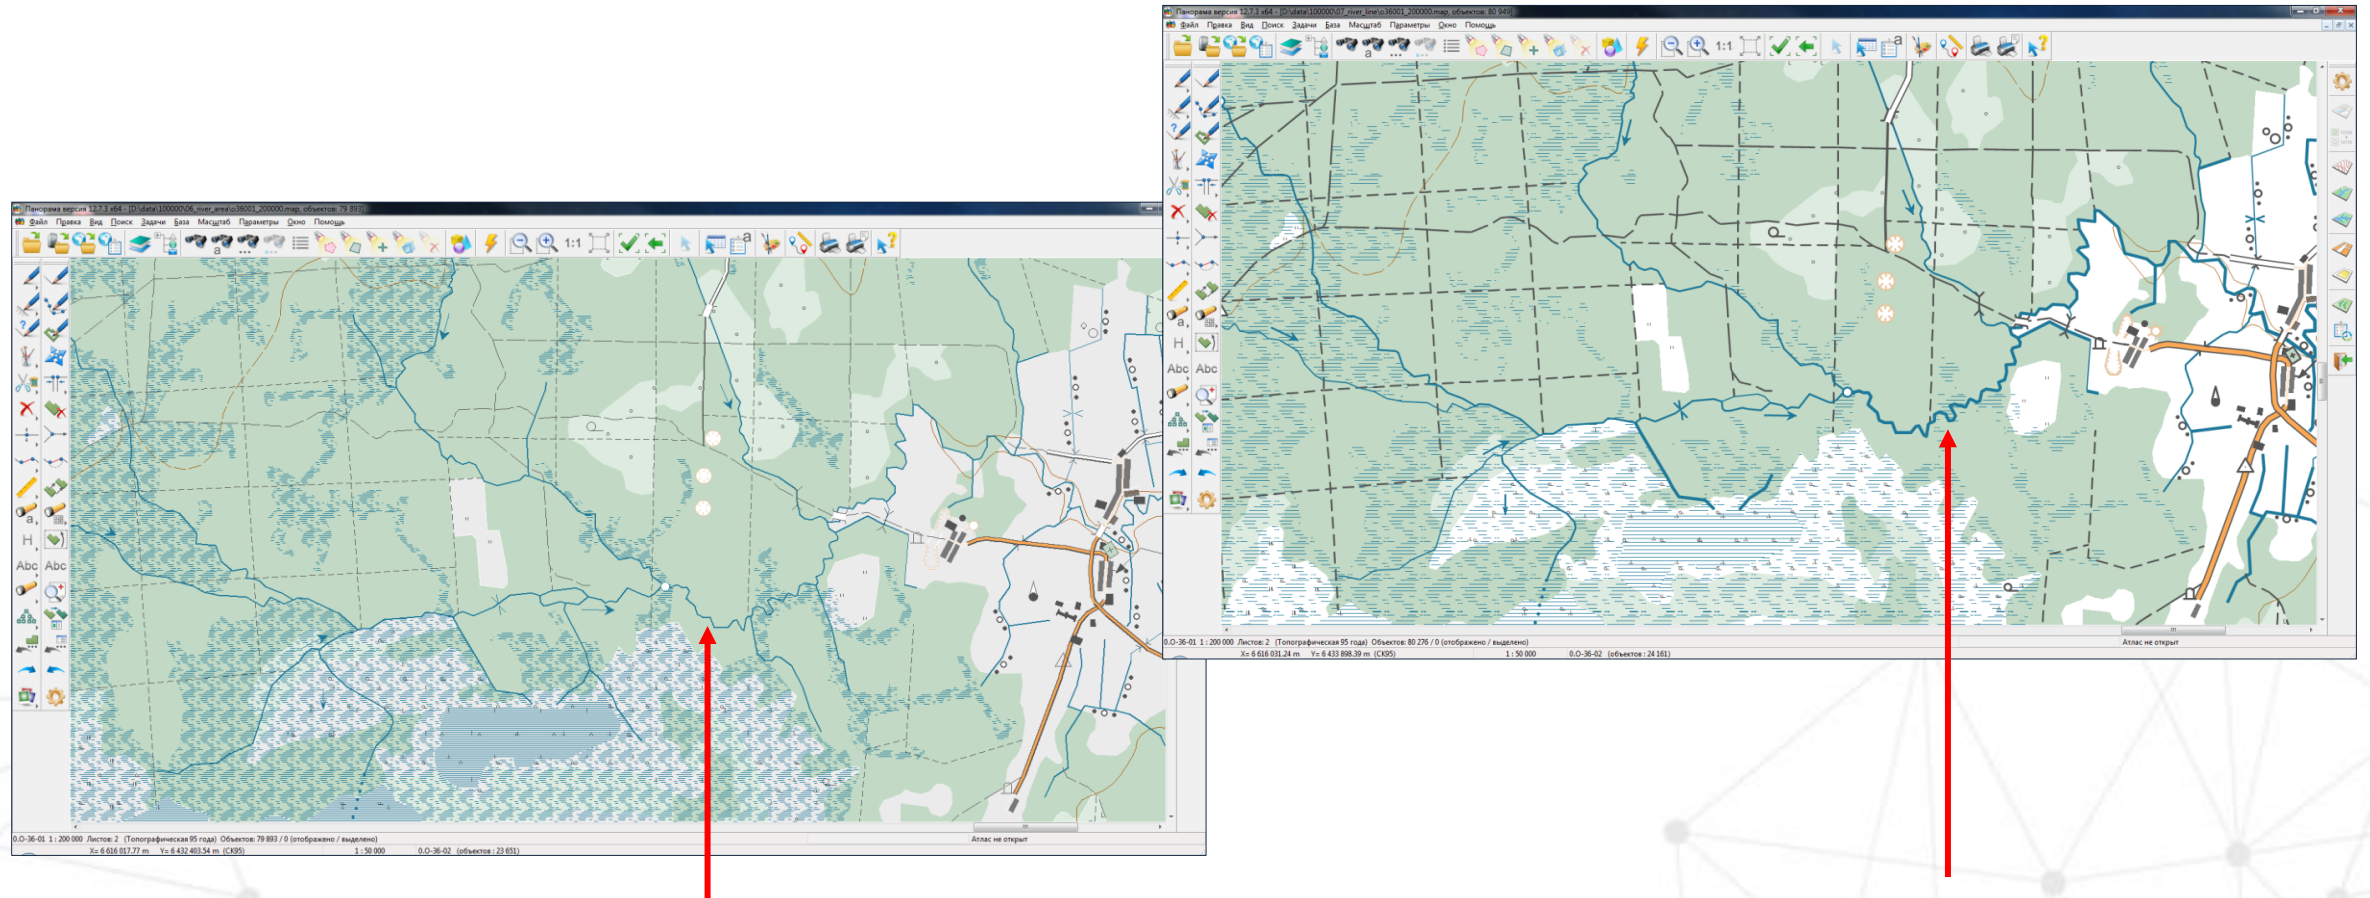

Automated generalization of areal rivers

When replacing a fragment of an areal river with a linear fragment, the metric of adjacent objects (areal forests and linear tributaries) is automatically matched

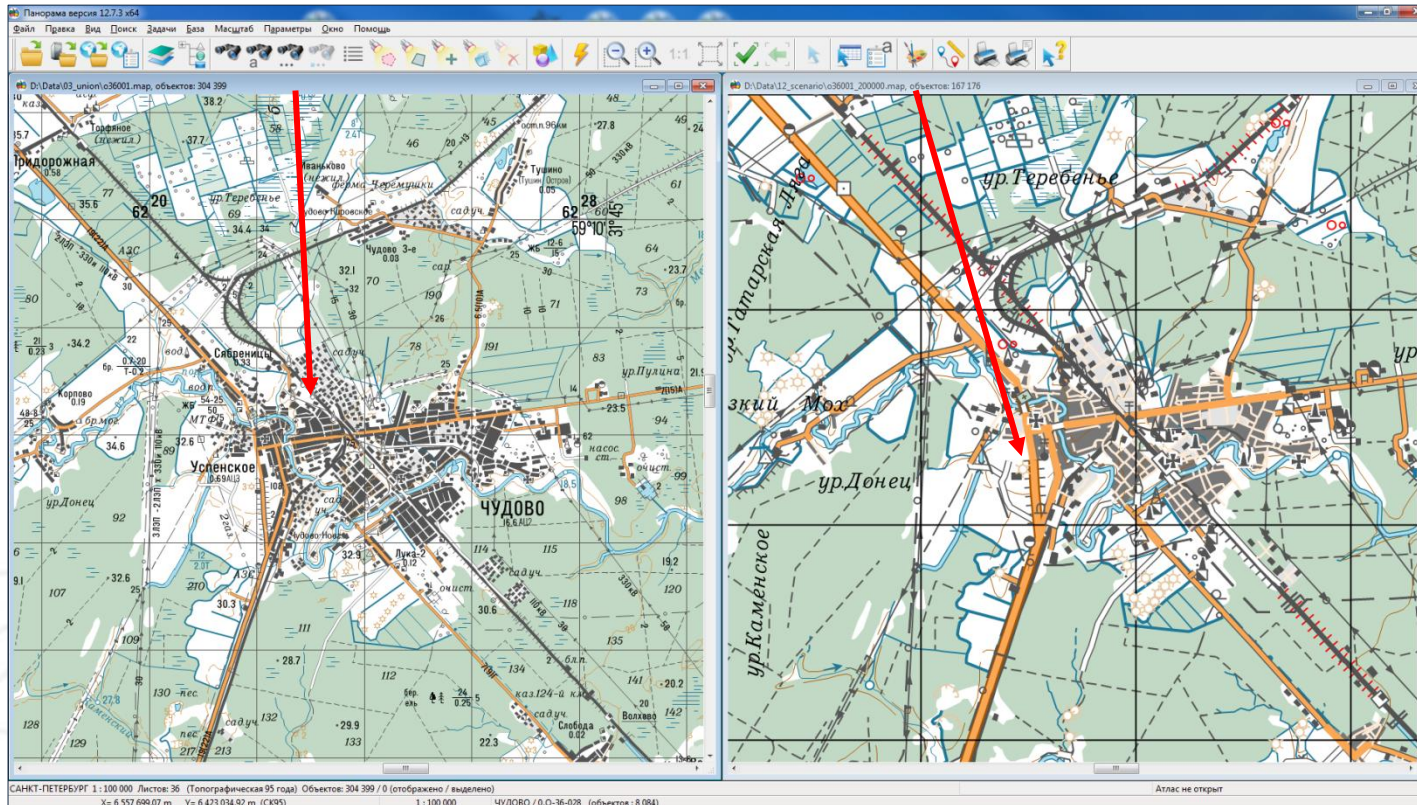

Automated generalization of linear rivers

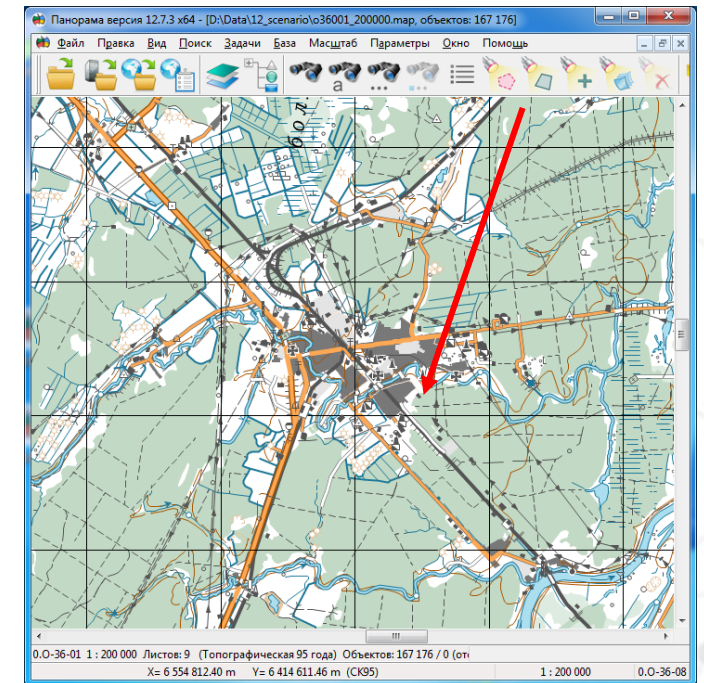

Linear rivers are broken into fragments between tributaries and a thickness - increasing from source to mouth – is assigned to each fragment

Automated generalization of road network

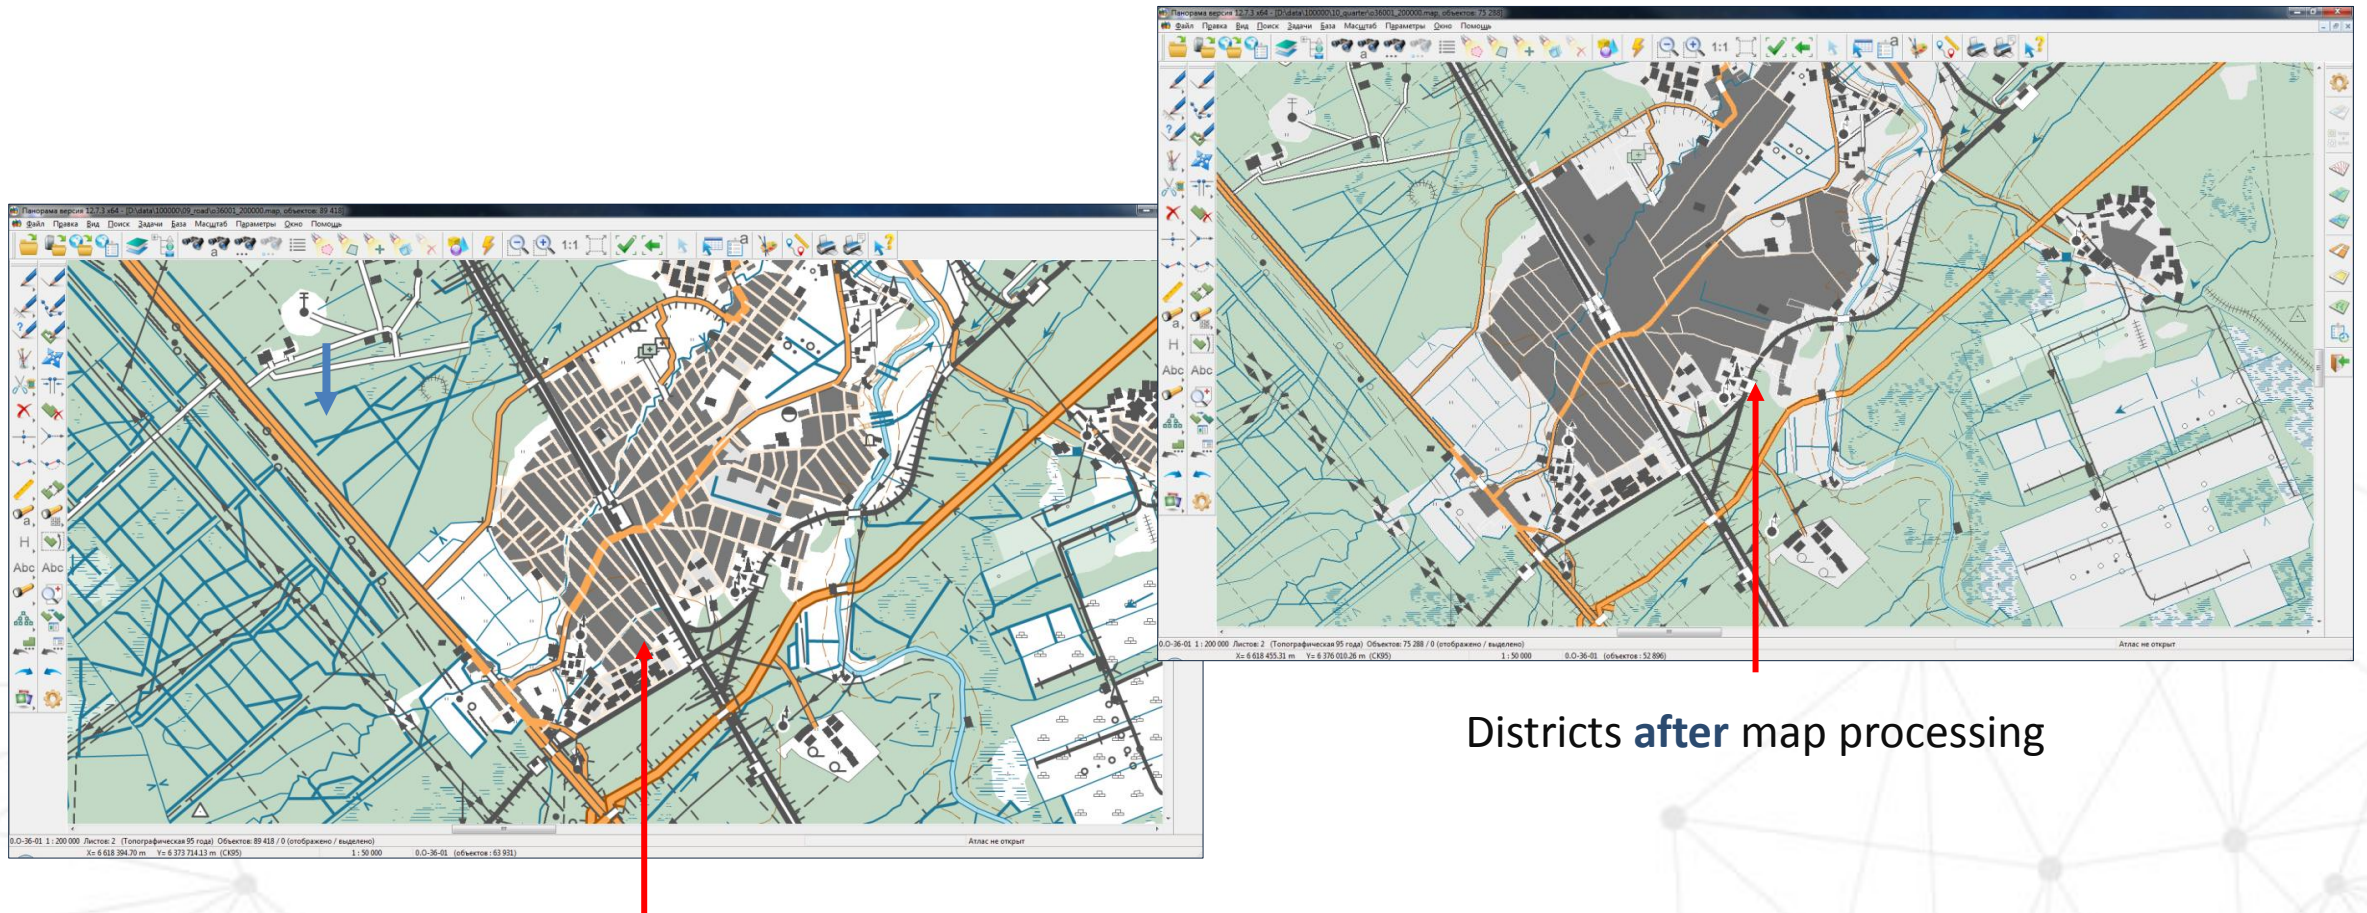

Settlement view in the 1 : 100 000 scale

Settlement view in the 1: 200 000 scale after map processing

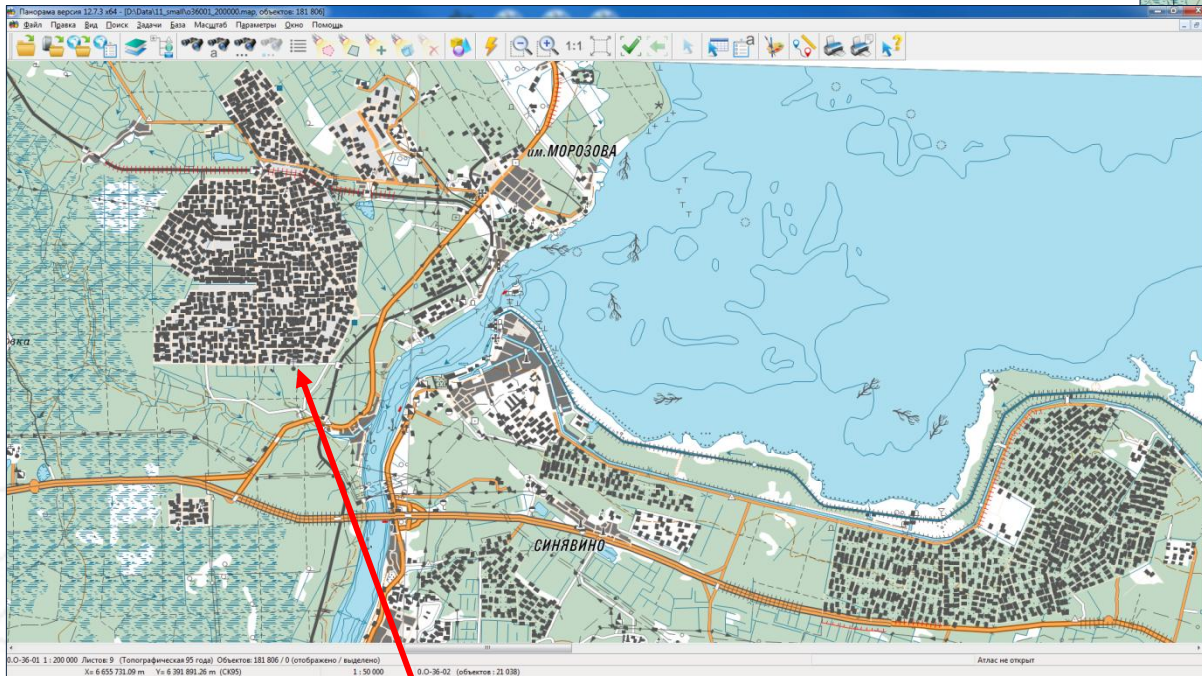

Automated generalization of urban settlements

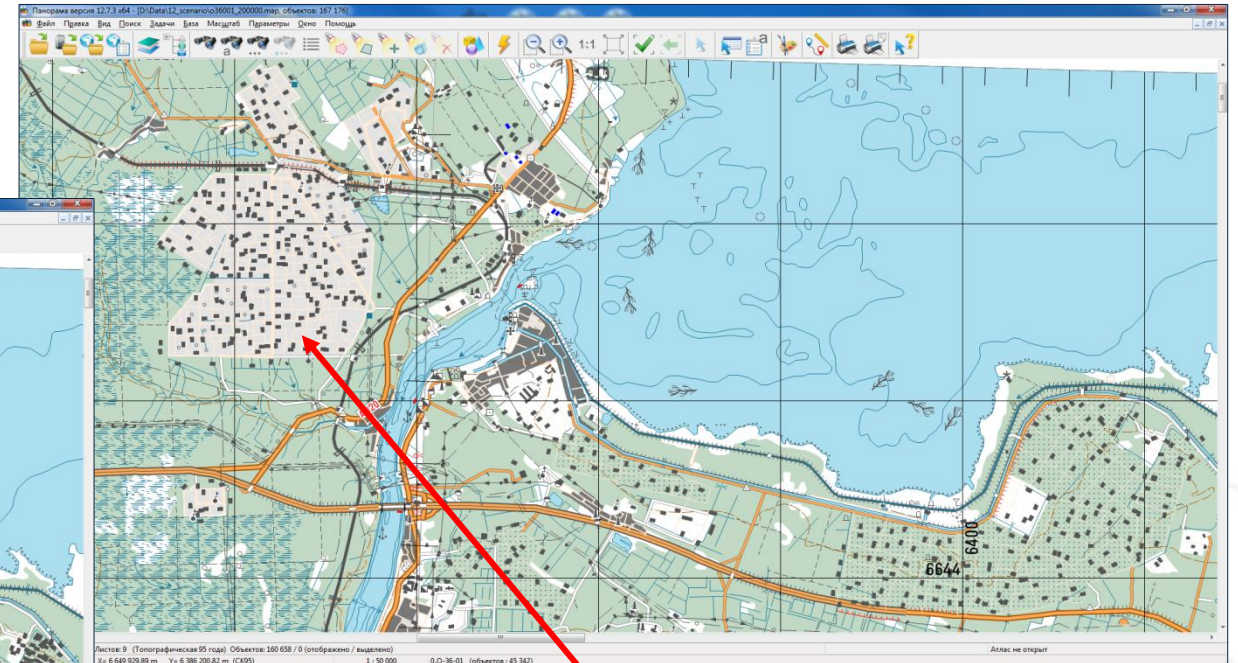

Districts **before** map processing

Districts **after** map processing

Generalization of buildings

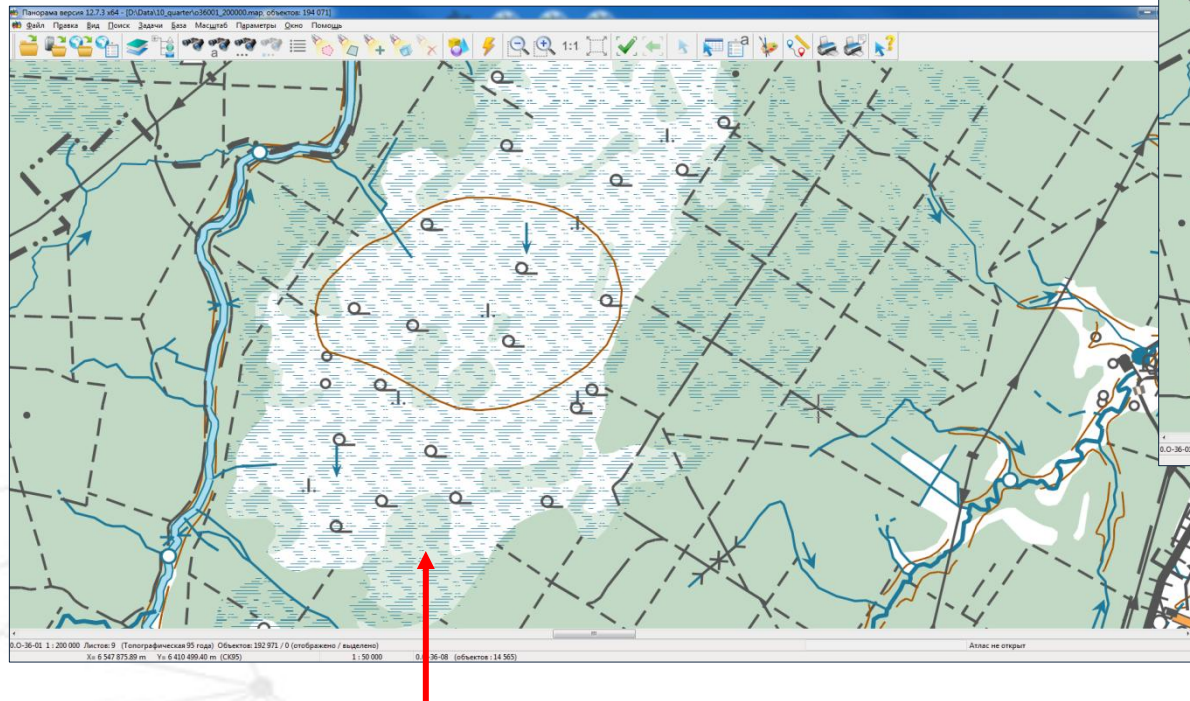

Rarefaction of buildings **before** processing

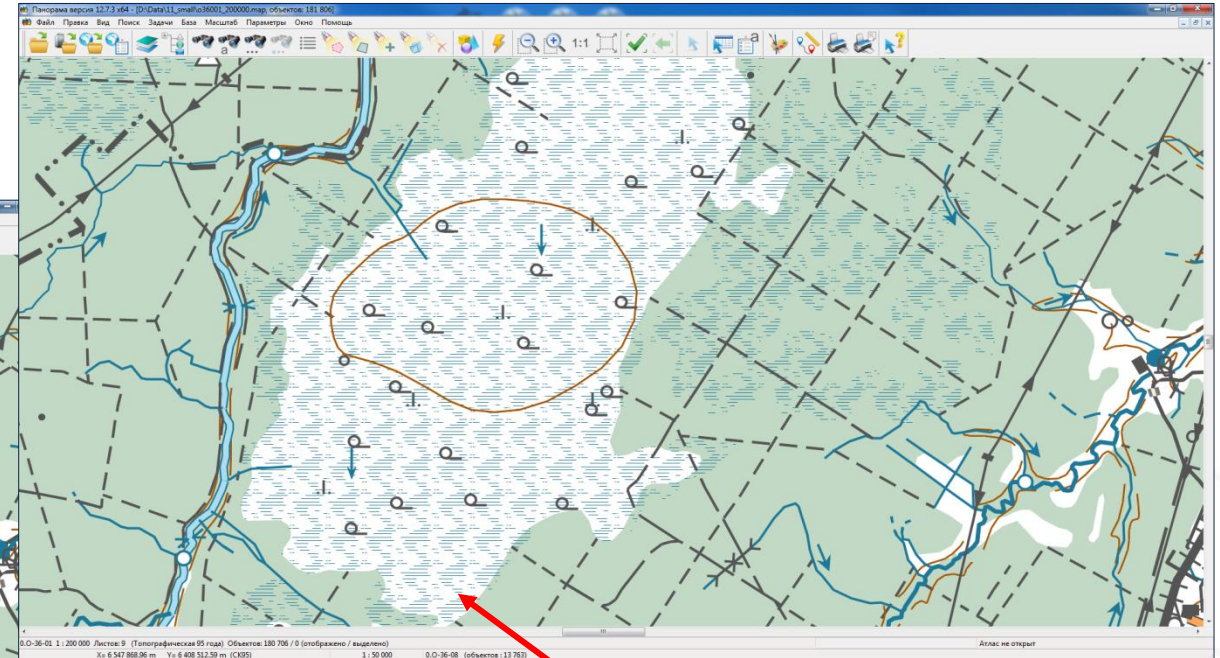

Rarefaction of buildings **after** processing

Automated generalization of small-form objects

Map type **before** processing

After processing the map lacks small-area objects (green forests in the swamps)

15
Min.

Takes the formation of 1 sheet of
derivative scale

*When converting 36 1:100000 scale map sheets to 9
1:200000 scale sheets
